An example of thermoelectric energy would be the conversion of a hot car engine exhaust to heat that can be used to generate electricity. Seebeck coefficient is a material property, and is a measure of its thermoelectric efficiency. The electrical resistance of a conductor is defined as the ratio of voltage to current flowing through a conductor, that is  $R = V/I$ . The first junction rectifier concept was patented in the United States in 1871 by Alexander Graham Bell. The availability of such power sources has transformed society in recent decades, particularly in the realm of consumer electronics. Thermoelectric technology provides the most energy-efficient means of converting heat into electricity, compared to other energy sources such as combustion engines. Thermoelectric energy generation is a viable and cost-effective alternative to fossil fuels to produce electricity at remote sites. With an estimated 250 terawatt-hours of this energy generated worldwide in 2015, it is smaller than total solar power generation, but the efficiency of thermoelectric technology is high. See also: In the United States, thermoelectric power is generated by the same companies that produce nuclear or coal-fired power plants. The basic concept has been commercialized in a few markets including specialized refrigerators and deep-sea research applications. The design of a thermoelectric generator is very similar to that of a battery, although the power generation takes place against a resistance. The design of a thermoelectric generator is very similar to that of a battery, although the power generation takes place against a resistance. The electrical power output is limited by the electrical resistance of the thermoelectric generators and this resistance increases when the temperature difference ( $\Delta T$ ) is reduced by impinging cooling air over the cooler side. A thermocouple across the coolerside will then increase the impedance mismatch and reduce the efficiency. By generating electricity from both sides of the thermocouple junction, the thermoelectric generator can tolerate large temperature differences without any problems. With an estimated 250 terawatt-hours of this energy generated worldwide in 2015, it is smaller than total solar power generation, but the efficiency of thermoelectric technology is high. Thermoelectric power is obtained by direct passage of a constant current into the legs of a thermoelectric device. On cooling, electrons exit the device, and the legs of the device become positively charged. Opposite charges of electrons and positively charged metals result in a current between the coolerside and the warmer side of the thermoelectric device. It is literally like mixing two liquids of different colors. Uranium's main uses are in the production of nuclear fuel and nuclear energy.
