
Ex4 To Mq4 Decompiler 4.0.427 [BETTER]

they have a special tool to extract xoring from the disassembler. it is not a decompiler, but a disassembler that will xor two streams of bytes together to produce the output. this lets you xor together a decompiler with another decompiler to get something like ex4 to mq4 decompiler, or even use xor to filter out a bad decompiler (if the above decompiler is bad, then the xoring still works).

when adding support for a new machine, the strategy would be to use a new register group and examine the different versions of the existing exe2ahk decompiler to see which of them fails to decompile. for the previous machine for ex4 to mq4 decompiler, ex4toahk.exe, a new register group called 'ex4toahk.exe' is expected. note that the original ahk decompilers (ie. the ones in the libraries part) are no longer available. i think they got combined with the new register group, and then they were deleted from the ghidra repository. the decompiler plugins break out the data into their own parts. if the user decompiles their code, then we can xor the output from an exe2ahk decompiler with the output from this plugin and get the resultant file. the decompilers are written in python, and will be packaged in separate python packages, distributed to pypi the same way as the original ex4 to mq4 decompiler. several of the decompiler subsystems are re-implemented in python for scalability and added apis, and for this reason most of the decompilers are probably better if they were written in python in the first place. the decompilers were written in go, but some of their subsystems could be (should be) rewritten in python, if they can be made to scale and work correctly. this will be done as a separate project that is unrelated to ex4mq4, but might in fact be part of it.

Ex4 To Mq4 Decompiler 4.0.427

a decompiler that works for static analysis is less useful. it cannot tell you whether the application behaves as expected without running the application. the best decompilers can get you the decompiled source code, but they can only tell you what the code is supposed to do. for example, an application may not actually behave as expected, or it may be hiding an attack, such as a buffer overflow. from a security perspective,

you might want to ensure that the application behaves as expected, and the best way to do that is to run it on an untrusted computer. this is where an ide is helpful, as the ide can write an application to a file, and then run it on the computer. this is what is done in the majority of reverse engineering. the decompiler cannot do this, but it can look at the disassembly and determine the behavior of the application. with the decompiler, you can see the application's code, and with the ide, you can see the effects of the decompilation. once you have the

debugging cli built, go to ghidra/features/decompiler/decomp_dbg and run the run action on the ex4 decompiler. depending on how many source files you have, this may take several minutes. if you prefer, you can use the wait action to quit the cli instead of running the run action. once the decompiler is running, open the decompilation db in the ghidra sqlite editor. you can get the path to the db with a single sql query, using the decomp_dbg/decomp_dbg.db property. this should be the first time that you connect to the db. once you

are connected, you can use the sqlite editor to inspect the db. 5ec8ef588b
